# Notes and exercises from Set Theory

#### John Peloquin

#### Introduction

This document contains notes and exercises from [1].

### Chapter 1

**Exercise** (1.2). There is no set *X* such that  $P(X) \subset X$ .

*Proof.* By the axiom of regularity (1.8), X is  $\in$ -minimal in  $\{X\}$ , so  $X \notin X$  and hence  $P(X) \notin X$ .

**Exercise** (1.3). If *X* is inductive, then the set  $\{x \in X \mid x \subset X\}$  is inductive. Hence *N* is transitive and for each  $n \in N$ ,  $n = \{m \in N \mid m < n\}$ .

*Proof.* Let  $S = \{x \in X \mid x \subset X\}$ . By inductivity of X,  $\emptyset \in S$ , and if  $x \in S$ , then  $x \cup \{x\} \in S$ , so S is inductive. Taking X = N, it follows that S = N since N is the smallest inductive set. Hence  $n \in N$  implies  $n \subset N$ , so N is transitive and  $n = \{m \in N \mid m < n\}$ . □

*Remark.* We proved transitivity of N "by induction" on N:  $0 \subseteq N$  and if  $n \subseteq N$  then  $n+1 \subseteq N$ , so  $n \subseteq N$  for all  $n \in N$ . The following exercises are similar.

**Exercise** (1.4). If X is inductive, then the set  $\{x \in X \mid x \text{ is transitive}\}$  is inductive. Hence every  $n \in N$  is transitive.

*Proof.* The class C of transitive sets is inductive. Indeed,  $\emptyset$  is transitive, and if x is transitive then  $x \cup \{x\}$  is transitive since  $y \in x \cup \{x\}$  implies  $y \subset x \subset x \cup \{x\}$ . It follows that  $\{x \in X \mid x \text{ is transitive}\} = X \cap C$  is inductive since the intersection of two inductive classes is inductive. Taking X = N, it follows as above that every  $n \in N$  is transitive.

**Exercise** (1.5). If *X* is inductive, then the set  $\{x \in X \mid x \text{ is transitive and } x \notin x\}$  is inductive. Hence  $n \notin n$  and  $n \neq n+1$  for all  $n \in N$ .

*Proof.* The class  $C = \{x \mid x \text{ is transitive and } x \notin x\}$  is inductive. Indeed,  $\emptyset \in C$ . If  $x \in C$ , then  $x \cup \{x\}$  is transitive (by inductivity of the class of transitive sets). Also  $x \cup \{x\} \notin x$ , lest  $x \cup \{x\} \subset x$  by transitivity of x and hence  $x \in x$ —contradicting  $x \notin x$ . Similarly  $x \cup \{x\} \neq x$ . Therefore  $x \cup \{x\} \notin x \cup \{x\}$ . So  $x \cup \{x\} \in C$ , and C is inductive. It follows as above that  $X \cap C$  is inductive, and taking X = N that  $n \notin n$  and hence  $n \neq n+1$  for all  $n \in N$ . □

*Remark.* In order to prove that  $n \notin n$  for all  $n \in N$  by induction on N, we "loaded the induction hypothesis" with transitivity.

**Exercise** (1.6). If X is inductive, then the set  $\{x \in X \mid x \text{ is transitive and regular}\}$  is inductive, where a set x is called *regular* if every nonempty subset of x has an  $\epsilon$ -minimal element.

*Proof.* The class  $C = \{x \mid x \text{ is transitive and regular}\}$  is inductive. Indeed,  $\emptyset \in C$ . If  $x \in C$ , then  $x \cup \{x\}$  is transitive. If  $y \subset x \cup \{x\}$  is nonempty, let  $z = y - \{x\} \subset x$ . If  $z = \emptyset$ , then  $y = \{x\}$ , and x is ∈-minimal in y by regularity of x. If  $z \neq \emptyset$  and t is ∈-minimal in x, then  $x \notin t$  by transitivity and regularity of x, so t is ∈-minimal in y. Therefore  $x \cup \{x\}$  is regular. So  $x \cup \{x\} \in C$ , and C is inductive. It follows as above that  $X \cap C$  is inductive.

*Remark.* Taking X = N it follows as above that every  $n \in N$  is regular.

**Exercise** (1.7). Every nonempty  $X \subset N$  has an  $\in$ -minimal element.

*Proof.* Choose  $n \in X$ . If n is not  $\epsilon$ -minimal in X, then  $n \cap X$  is a nonempty subset of n, which has an  $\epsilon$ -minimal element m (Exercise 1.6). By transitivity of n (Exercise 1.4), m is  $\epsilon$ -minimal in X.

**Exercise** (1.8). If *X* is inductive, then the set  $\{x \in X \mid x = \emptyset \text{ or } \exists y(x = y \cup \{y\})\}$  is inductive. Hence for all  $n \in \mathbb{N}$ , n = 0 or n = m + 1 for some  $m \in \mathbb{N}$ .

*Proof.* The class  $C = \{x \mid x = \emptyset \text{ or } \exists y(x = y \cup \{y\})\}$  is obviously inductive, so  $X \cap C$  is inductive. Taking X = N, the rest follows, with  $m \in N$  by transitivity of N (Exercise 1.3). □

**Exercise** (1.9). Let  $A \subset N$  be such that  $0 \in A$ , and if  $n \in A$  then  $n + 1 \in A$ . Then A = N.

*Proof.* A is inductive, so A = N since N is the smallest inductive set.

Alternately, if  $A \neq N$ , let m be  $\in$ -minimal in N-A (Exercise 1.7). Then  $m \neq 0$ , and  $m \neq n+1$  for any  $n \in N$ , which is impossible (Exercise 1.8).

**Exercise** (1.10). Each  $n \in N$  is T-finite.

*Proof.* By induction on N. First, n = 0 is T-finite since  $P(\emptyset) = \{\emptyset\}$  and  $\emptyset$  is  $\subseteq$  maximal in  $\{\emptyset\}$ . If n is T-finite, suppose  $X \subseteq P(n \cup \{n\})$  is nonempty. Let

$$X' = \{ u - \{ n \} \mid u \in X \}$$

Then  $X' \subset P(n)$  is nonempty and has a  $\subset$ -maximal element  $u - \{n\}$  for some  $u \in X$  by T-finiteness of n, where we may assume  $n \in u$  if  $u \cup \{n\} \in X$ . We claim u is  $\subset$ -maximal in X. Indeed, if  $v \in X$  and  $u \subset v$ , then  $u - \{n\} \subset v - \{n\}$ , so  $u - \{n\} = v - \{n\}$  by  $\subset$ -maximality of  $u - \{n\}$  in X', so u = v by the assumption about u. Therefore n + 1 is T-finite.

**Exercise** (1.11). *N* is T-infinite. In fact,  $N \subset P(N)$  has no  $\subset$ -maximal element.

*Proof.* We know  $N \subset P(N)$  by transitivity of N (Exercise 1.3), and for all  $n \in N$  we have  $n \subset n+1 \in N$  but  $n \neq n+1$  (Exercise 1.5).

*Remark.* If A is T-finite and  $\pi: A \to B$  is surjective (onto), then B is T-finite.

*Proof.* By pullback. If  $X \subset P(B)$  is nonempty, let

$$X_{-1} = \pi_{-1}(X) = \{ u_{-1} = \pi_{-1}(u) \mid u \in X \}$$

Then  $X_{-1} \subset P(A)$  is nonempty and has a  $\subset$ -maximal element  $u_{-1}$  for some  $u \in X$  by T-finiteness of A. We claim u is  $\subset$ -maximal in X. Indeed, if  $v \in X$  and  $u \subset v$ , then  $u_{-1} \subset v_{-1}$ , so  $u_{-1} = v_{-1}$  by  $\subset$ -maximality of  $u_{-1}$  in  $u_{-1}$ , so u = v by surjectivity of u. Therefore u is T-finite.

**Exercise** (1.12). Every finite set is T-finite.

*Proof.* By definition, every finite set is the image of a T-finite natural number (Exercise 1.10), so is T-finite by the previous remark.

Alternately, if S is T-infinite, choose  $X \subset P(S)$  nonempty with no  $\subset$ -maximal element. By induction on N, for each  $n \in N$  there is a properly ascending chain  $u_0 \subset \cdots \subset u_n \subset S$  of length n+1 in X, and hence an injection  $n \to S$  sending  $m \in n$  into  $u_{m+1} - u_m$ . If S had k elements for some  $k \in N$ , there would then be an injection  $k+1 \to k$ , which is impossible by an easy induction on k. Therefore S is infinite.

**Exercise** (1.13). Every infinite set is T-infinite.

*Proof.* If *S* is infinite, let *X* be the set of finite subsets of *S*. Clearly *X* is nonempty since  $\emptyset \in X$ . Also *X* has no ⊂-maximal element. Indeed, if  $u \in X$  then there is  $s \in S - u$  since *S* is infinite, and  $u \cup \{s\}$  is finite (if *u* has *k* elements, then  $u \cup \{s\}$  has k + 1 elements), so  $u \subset u \cup \{s\} \in X$  where the inclusion is proper. Therefore *S* is T-infinite.

*Remark.* The previous two exercises show that (Cantor) finiteness is equivalent to Tarski finiteness in ZF.

#### Chapter 2

*Remark.* In (2.1), < is actually a *well-ordering* on *Ord*. Indeed, if  $C \subset Ord$  is a nonempty class of ordinals and  $\alpha \in C$  is not  $\in$ -minimal in C, then  $\alpha \cap C$  is a nonempty subset of  $\alpha$  which has an  $\in$ -minimal element  $\beta$ . By transitivity of  $\alpha$ ,  $\beta$  is  $\in$ -minimal in C.

This observation provides an alternative proof that Ord is a proper class: if Ord were a set, then because it is transitive and strictly well-ordered by  $\in$ , it would be an ordinal, and hence  $Ord \in Ord$ —contradicting strictness.

**Exercise** (2.2).  $\alpha$  is a limit ordinal if and only if  $\beta < \alpha$  implies  $\beta + 1 < \alpha$  for all  $\beta$ .

*Proof.* If  $\alpha$  is a limit ordinal and  $\beta < \alpha$ , then  $\beta + 1 \le \alpha$  (2.5) and  $\beta + 1 \ne \alpha$ , so  $\beta + 1 < \alpha$ . If  $\alpha$  is not a limit ordinal, then  $\beta + 1 = \alpha$  for some  $\beta < \alpha$ .

*Remark.* It follows that  $\alpha$  is a nonzero limit ordinal if and only if it is inductive.

**Exercise** (2.3). If *X* is inductive, then  $X \cap Ord$  is inductive. *N* is the least nonzero limit ordinal, where  $N = \bigcap \{X \mid X \text{ inductive}\}.$ 

*Proof.* Clearly Ord is inductive, so  $X \cap Ord$  is inductive since the intersection of two inductive classes is inductive. Taking X = N, it follows that  $N \subset Ord$ , and since N is also transitive, N is an ordinal. By the previous remark, N is the least nonzero limit ordinal.

**Exercise** (2.4). (Without the axiom of infinity.) Let  $\omega$  be the least nonzero limit ordinal, if it exists, or *Ord* otherwise. The following are equivalent:

(i) There exists an inductive set.

- (ii) There exists an infinite<sup>1</sup> set.
- (iii)  $\omega$  is a set.

*Proof.* (i)  $\iff$  (iii): The smallest inductive set is the least nonzero limit ordinal (Exercise 2.3).

- (iii)  $\Longrightarrow$  (ii):  $\omega$  is infinite (Exercises 1.11–2).
- (ii)  $\implies$  (i): For any finite set A, let |A| denote the least  $n \in \omega$  in bijective correspondence with A (the "number of elements" in A). If X is infinite, let

$$S = \{ |A| \mid A \subset X \text{ finite} \}$$

Note *S* is a set by replacement, and *S* is inductive. Indeed,  $0 \in S$  since  $\emptyset \subset X$  and  $|\emptyset| = 0$ . If  $n \in S$  and  $A \subset X$  with |A| = n, then there must exist  $x \in X - A$  since *X* is infinite, and  $|A \cup \{x\}| = n + 1 \in S$ .

*Remark.* This exercise shows that (i)–(iii) are equivalent forms of the axiom of infinity in ZF.

**Exercise** (2.5). If W is a well-ordered set, then there is no sequence  $\langle a_n \mid n \in \mathbb{N} \rangle$  in W such that  $a_0 > a_1 > \cdots$ .

*Proof.* If there were such a sequence, then  $\{a_n \mid n \in N\}$  would be a nonempty subset of W with no least element, contradicting well-ordering.

**Exercise** (2.6). There are arbitrarily large limit ordinals.

*Proof.* Given  $\alpha$ , let  $\beta = \alpha + \omega$ . Clearly  $\beta > \alpha$ . If  $\gamma < \beta$ , then either  $\gamma < \alpha$ , in which case  $\gamma + 1 < \alpha + 1 < \beta$ , or  $\gamma \ge \alpha$ , in which case  $\gamma = \alpha + n$  for some  $n \in \omega$  (Lemma 2.25), so  $\gamma + 1 = \alpha + n + 1 < \beta$ . Thus  $\beta$  is a limit ordinal (Exercise 2.2).  $\square$ 

*Remark* (Chain rule). If  $f,g: Ord \to Ord$  are nondecreasing and continuous, then so is  $f \circ g$ . If f and g are normal, then so is  $f \circ g$ .

*Proof.* If  $\alpha < \beta$ , then  $g(\alpha) \le g(\beta)$ , so  $f(g(\alpha)) \le f(g(\beta))$ . Let  $\alpha$  be a nonzero limit ordinal. Clearly  $f(g(\alpha)) \ge \lim_{\xi \to \alpha} f(g(\xi))$ . If  $g(\alpha) = g(\xi')$  for some  $\xi' < \alpha$ , then  $f(g(\alpha)) = f(g(\xi')) \le \lim_{\xi \to \alpha} f(g(\xi))$ . Otherwise,  $g(\alpha)$  is a limit ordinal. Indeed,  $g(\alpha) = \lim_{\xi \to \alpha} g(\xi)$  by continuity of g, so if  $\beta < g(\alpha)$ , then  $\beta < g(\xi)$  for some  $\xi < \alpha$ , and hence  $\beta + 1 \le g(\xi) < g(\alpha)$ . But then  $f(g(\alpha)) = \lim_{\xi \to g(\alpha)} f(\xi)$  by continuity

<sup>&</sup>lt;sup>1</sup>In this exercise, a set is *finite* if it is in bijective correspondence with some n ∈ ω and *infinite* otherwise, even if ω = Ord.

of f. If  $\zeta < g(\alpha)$ , then  $\zeta < g(\xi)$  for some  $\xi < \alpha$ , so  $f(\zeta) \le f(g(\xi))$ , and hence  $\lim_{\zeta \to g(\alpha)} f(\zeta) \le \lim_{\xi \to \alpha} f(g(\xi))$ . Therefore again  $f(g(\alpha)) = \lim_{\xi \to \alpha} f(g(\xi))$  and  $f \circ g$  is continuous.

If f and g are also increasing, then  $f \circ g$  is increasing and hence normal.  $\square$ 

**Exercise** (2.7). Every normal sequence  $\langle \gamma_{\alpha} \mid \alpha \in Ord \rangle$  has arbitrarily large fixed points (that is,  $\beta$  such that  $\gamma_{\beta} = \beta$ ).

*Proof.* Given  $\alpha$ , let  $\beta_0 = \gamma_\alpha$  and  $\beta_{n+1} = \gamma_{\beta_n}$  for all  $n \in \omega$ . Note  $\beta_{n+1} \ge \beta_n \ge \alpha$  for all  $n \in \omega$  since  $\gamma$  is increasing (Lemma 2.4). Let  $\beta = \lim_{n \to \omega} \beta_n$ . Then

$$\gamma_{\beta} = \lim_{n \to \omega} \gamma_{\beta_n} = \lim_{n \to \omega} \beta_{n+1} = \beta$$

by the chain rule above (taking  $\beta_{\alpha} = \beta$  for all  $\alpha \ge \omega$ ).

**Exercise** (2.8). For all  $\alpha, \beta, \gamma$ :

(i) 
$$\alpha \cdot (\beta + \gamma) = \alpha \cdot \beta + \alpha \cdot \gamma$$

(ii) 
$$\alpha^{\beta+\gamma} = \alpha^{\beta} \cdot \alpha^{\gamma}$$

(iii) 
$$(\alpha^{\beta})^{\gamma} = \alpha^{\beta \cdot \gamma}$$

*Proof.* By induction on  $\gamma$ .

(i) If  $\gamma = 0$ ,

$$\alpha \cdot (\beta + \gamma) = \alpha \cdot (\beta + 0) = \alpha \cdot \beta = \alpha \cdot \beta + 0 = \alpha \cdot \beta + \alpha \cdot 0 = \alpha \cdot \beta + \alpha \cdot \gamma$$

If the result holds for  $\gamma$ , then

$$\alpha \cdot (\beta + (\gamma + 1)) = \alpha \cdot ((\beta + \gamma) + 1)$$
 by associativity of + 
$$= \alpha \cdot (\beta + \gamma) + \alpha$$
 by definition of \cdot 
$$= (\alpha \cdot \beta + \alpha \cdot \gamma) + \alpha$$
 by hypothesis 
$$= \alpha \cdot \beta + (\alpha \cdot \gamma + \alpha)$$
 by associativity of + 
$$= \alpha \cdot \beta + \alpha \cdot (\gamma + 1)$$
 by definition of \cdot

so the result holds for  $\gamma + 1$ . If  $\gamma$  is a nonzero limit ordinal and the result holds for all  $\xi < \gamma$ , then

$$\begin{split} \alpha \cdot (\beta + \gamma) &= \lim_{\xi \to \gamma} \alpha \cdot (\beta + \xi) & \text{by continuity of } \xi \mapsto \alpha \cdot (\beta + \xi) \\ &= \lim_{\xi \to \gamma} (\alpha \cdot \beta + \alpha \cdot \xi) & \text{by hypothesis} \\ &= \alpha \cdot \beta + \alpha \cdot \gamma & \text{by continuity of } \xi \mapsto \alpha \cdot \beta + \alpha \cdot \xi \end{split}$$

so the result holds for  $\gamma$ . Note that continuity of the composite mappings involved follows from continuity of addition and multiplication and the chain rule above.

- (ii) Similar.
- (iii) Similar, using (i) and (ii) in the successor step.
